(54) Title: BICYCLIC OXAZOLIDINONES AS ANTIBACTERIAL AGENT

(I)

(57) Abstract: The present invention provides compounds  
of formula (I) useful as antimicrobial agents wherein W, X,  
Y, R<sup>1</sup>, R<sup>2</sup> and n are as defined in thereof.

## BICYCLIC OXAZOLIDINONES AS ANTIBACTERIAL AGENT

## FIELD OF THE INVENTION

The present invention relates to novel bicyclic oxazolidinone compounds and their  
5 preparations, more specifically, to R<sup>1</sup>-substituted bicyclic oxazolidinones as shown in  
formula I. These compounds have potent activities against gram positive and gram-  
negative bacteria.

## BACKGROUND OF THE INVENTION

10 The oxazolidinone antibacterial agents are a novel synthetic class of antimicrobials  
with potent activity against a number of human and veterinary pathogens, including  
gram-positive aerobic bacteria such as multiply-resistant staphylococci and streptococci,  
anaerobic organisms such as bacteroides and clostridia species, and acid-fast organisms  
such as *Mycobacterium tuberculosis* and *Mycobacterium avium*.

15 However, oxazolidinones generally do not demonstrate an activity at a useful level  
against aerobic gram-negative organisms. Thus, the use of these oxazolidinone  
antibacterial agents is limited to infectious states due to gram-positive bacteria.  
Accordingly, it is among the objects of the present invention to provide pharmaceutical  
compounds which have broader antibacterial activity including the activity against aerobic  
20 gram-negative organisms. We have now discovered that the incorporation of a R<sup>1</sup> group at  
the bicyclic oxazolidinone imparts an unexpected increase in antibacterial activity as well as  
in the spectrum of activity to include gram-negative organisms such as *Haemophilus*  
*influenza* and *Moraxella catarrhalis*. More importantly, this increase in the potency and  
spectrum of activity is only seen in the specified diastereomers of formula I.

## 10 DETAILED DESCRIPTION OF THE INVENTION

The following definitions are used, unless otherwise described.

The term halo refers to fluoro, chloro, bromo, or iodo.

The term alkyl, alkoxy, etc. refer to both straight and branched groups, but reference to an individual radical such as "propyl" embraces only the straight chain radical, a branched chain isomer such as "isopropyl" being specifically referred to.

The carbon atom content of various hydrocarbon-containing moieties is indicated by a prefix designating the minimum and maximum number of carbon atoms in the moiety, i.e., the prefix C<sub>i-j</sub> indicates a moiety of the integer "i" to the integer "j" carbon atoms, inclusive. Thus, for example, C<sub>1-7</sub> alkyl refers to alkyl of one to seven carbon atoms, inclusive.

The compounds of the present invention are generally named according to the IUPAC or CAS nomenclature system. Abbreviations which are well known to one of ordinary skill in the art may be used (e.g. "Ph" for phenyl, "Me" for methyl, "Et" for ethyl, "h" for hour or hours and "rt" for room temperature).

It will be appreciated by those skilled in the art that compounds of the present may have additional chiral centers and be isolated in optically active or racemic form. The present invention encompasses any racemic, optically-active (such as enantiomers, diastereomers), tautomeric, or stereoisomeric form, or mixture thereof, of a compound of the invention.

## INDOLINES

As shown in Chart I, 2-alkylindolines can be prepared from known compound indole **1**. Boc-protection of the indole nitrogen using di-*t*-butyldicarbonate and catalytic DMAP followed by regioselective metalation with *n*-butyllithium, *sec*-butyllithium or *tert*-butyllithium and alkylation with an appropriate electrophile such as alkyl bromides and iodides gives N-Boc-2-alkylindoles **3** (R is an alkyl or a electrophile group). Removal of the boc-protecting group affords 2-alkylindoles **4** which can be nitrated with NaNO<sub>3</sub> in sulfuric acid to give 2-alkyl-5-nitroindoles **5**. Structure **5** is then reacted with sodium cyanoborohydride to give reduction product, the racemic indolines **6**. The nitro group can then be reduced by catalytic hydrogenation in the presence of a suitable catalyst, such as palladium on carbon in a suitable solvent such as ethylacetate, THF, methanol or combinations thereof to afford the 2-alkyl-5-aminoindolines **7** as racemic mixtures. Treatment of **7** with benzyl chloroformate (2 equivalents) in THF with an appropriate base, such as sodium bicarbonate, potassium carbonate or triethylamine gives the bis-Cbz-protected materials of general structure **8**. Alternatively, the intermediate R,S-2-alkylnitroindolines can be separated via chiral HPLC to afford enantiomerically pure R- and

S-2-alkyl-5-nitroindolines **9** and **10**. These materials can then be taken on separately in a chiral synthesis of the desired analogs.

In addition, where other groups besides alkyl are desired at the 2-position of the indoline, one can start with the known ethyl 5-nitroindole-2-carboxylate **11** (Chart II).

- 5 Reduction of the nitro group to ethyl 5-aminoindole-2-carboxylate can be done via hydrogenation. Structure **12** then be reduced to the indoline intermediate **13** according to the procedure of Young et.al. (Tetrahedron Lett. **1986**, 27, 2409-2410) with magnesium in methanol. Bis-protection of the nitrogens with the Cbz-group using benzyl chloroformate provides **14**. Reduction of the ester to the alcohol **15** with an appropriate base such as
- 10 LAH, NaBH<sub>4</sub> or DIBAL in a solvent such as diethyl ether or THF or methanol can then be done. Protection of the hydroxyl group with an appropriate protecting group (R') such as a silyl or benzyl ether provides **16**.

- The protected indolines thus prepared can be converted to the final oxazolidinone analogs as outlined in Chart III (R is H, an alkyl group or OR'; wherein R' is a protecting
- 15 group). The carbamate derivatives **8**, **16** and **18** can be deprotonated with a lithium base such as n-butyllithium, lithium diisopropylamide (LDA), or lithium bis(trimethylsilyl)amide (LHMDS) in a suitable solvent such as THF, N,N-dimethylformamide (DMF), or mixtures thereof, at a suitable temperature, typically in a range from -78°C to -40°C to give a lithiated intermediate which is directly treated with R-(-)-glycidyl butyrate. Warming to
- 20 room temperature then affords (hydroxymethyl)oxazolidinones **19**. In cases where racemic starting materials are used, compound **19** is obtained as a mixture of two diastereoisomers. In the event that enantiomerically pure intermediates are employed, compound **19** is obtained as one diastereomer. The diastereomeric mixtures of (hydroxymethyl)-oxazolidinones **19** can be separated via chiral HPLC into single compounds and crystallized
- 25 in an appropriate solvent such as CHCl<sub>3</sub>, Et<sub>2</sub>O, CH<sub>2</sub>Cl<sub>2</sub>, hexane, alcohol, ethyl acetate, THF, acetone or a mixture of them thereof to obtain x-ray structures to determine the absolute stereochemistry.

- As shown in Chart III, the hydroxymethyl derivatives can be converted to the corresponding mesylate **20** (R' = Me) or nosylate **20** (R' = 3-NO<sub>2</sub>Ph) by treatment with
- 30 methanesulfonyl chloride in the presence of triethylamine or pyridine, or meta-nitrophenylsulfonyl chloride in the presence of pyridine respectively. The resulting sulfonate **20** can be treated with an alkali metal azide, such as potassium or sodium azide in an aprotic solvent such as DMF, or N-methylpyrrolidinone (NMP) with an optional catalyst

such as 18-crown-6 at a temperature in the range of 50-90°C to afford azides **21**. The azides can be reduced to the corresponding amine **22** by hydrogenation in the presence of a palladium, platinum or nickel catalyst, in an appropriate solvent such as THF, ethyl acetate, or methanol. Alternatively, azides **21** can be reduced to amines **22** by treatment with

5 triphenylphosphine or other trivalent phosphorous compounds in a solvent such as THF, followed by addition of water and heating to temperatures up to 65°C. A more direct route to the amines **22** is to reflux the sulfonates **20** in isopropanol/THF/ammonium hydroxide under a dry ice/acetone condenser. The amines **22** thus obtained can be acylated by reactions well known to those skilled in the art to give (acylaminomethyl)oxazolidinones of

10 structural formula **23**. It can also be seen that other acyl derivatives, such as carbamates, can be prepared under similar conditions. Furthermore, treatment of intermediates **23** (W = O) with Lawesson's reagent in refluxing toluene or THF will afford thioamides **23** (W = S). The Cbz-group of the (acylaminomethyl)oxazolidinones **23** can be removed via hydrogenation in the presence of an appropriate catalyst such as palladium on carbon in

15 solvents such as THF, methanol, ethyl acetate, dichloromethane or mixtures thereof to afford deprotected intermediates of general structure **24**. Alternatively, solvolysis of Cbz-derivatives **23** in 40% HBr/acetic acid followed by removal of solvent provides deprotected intermediates **24** as hydrobromide salts. The deprotected materials can be acylated by reactions well known to those skilled in the art to give oxazolidinones of structural formula

20 **25** ( $R^3 = \text{acyl}$ ). It can also be seen that other acyl derivatives, such as carbamates, can be prepared under similar conditions. In addition, the deprotected materials can be alkylated by reactions well known to those skilled in the art to give oxazolidinones of structural formula **25** ( $R^3 = \text{alkyl}$ ).

Where other substitution on the 2-position of the indoline is desired, the protected

25 alcohol derivatives **25** ( $R = \text{OSiR}_3$ , or OBn) can be deprotected with fluoride in the case of the silyl ethers or catalytic hydrogenation in the case of the benzyl ethers. The resulting alcohols **26** can be alkylated to prepare other ether derivatives **27** ( $R''' = \text{O-alkyl}$ ) or acylated to give esters **27** ( $R''' = \text{O-acyl}$ ). Alternatively, they can be activated as sulfonates and displaced with nucleophiles to yield aminomethyl derivatives **27** ( $R''' = \text{NH}_2$  or

30 NHalkyl) which can be acylated, sulfonylated and/or alkylated to give **27** ( $R''' = \text{NHCOH}$ , NHCOalkyl, NHSO<sub>2</sub>alkyl) by methods well known to those trained in the art. Finally, such alcohols may be converted to the fluoro derivative via treatment with (diethylamino)sulfur trifluoride.

## BENZTHIOPHENES

Chart IV ( $R^1$  is as defined above and  $R'$  is a protecting group) shows the synthesis of 2-substituted-2,3-dihydro-1-benzothiophene intermediates **33** and **39**. Aniline **29** can be prepared by reacting a known compound, methyl 5-nitro-1-benzothiophene-2-carboxylate **28** (Syn. Comm. **1991**, *21*, 959-964), with Raney nickel or stannous chloride in refluxing ethanol. Cbz-protection and reduction to the benzothiophene **31** can be obtained according to the method described in Youn et.al. (Tetrahedron Lett. **1986**, *27*, 2409-2410) using magnesium in methanol. Following the procedure described in Chart II, ester **31** can be converted to the protected alcohol **33**. If desired, the sulfur atom can be oxidized to the sulfoxide or sulfone at various stages in the synthesis by methods well known to those skilled in the art.

Alternatively, the requisite 2-substituted benzothiophenes can be prepared via thio-Claisen rearrangement of allyl aryl sulfoxides **37** (J.C.S. Chem. Comm. **1974**, 850). The requisite allylic sulfides **36** can be prepared from a commercially available compound, 4-aminothiophenol, to give structure **35**, via the protection of the aniline with benzyl chloroformate. The allylation of the sulfide with allylic halides provides **36** which can be oxidized to the sulfoxides **37** with a sodium periodate. Thermal rearrangement in an appropriate solvent such as dimethylaniline or DMF at temperatures ranging from 100 - 150°C provides the desired intermediates **38**. The sulfoxide can be maintained throughout the synthesis or it can be reduced to the sulfides **39** at this time via various methods such as using NaI and trifluoroacetic anhydride in acetone (J. Org. Chem **1994**, *58*, 3459-3466); or  $BF_3 \cdot OEt_2$  and NaI in acetonitrile (Tetrahedron Asymmetry **1997**, *8*, 3503-3511); or triphenylphosphine and catalytic  $ReOCl_3(PPh_3)_2$  in dichloromethane (Tetrahedron Lett. **1996**, 7941-7944). The remaining steps which lead **33** and **39** to the desired oxazolidinone analogs of type **40a** and **40b** are similar to these described in Charts I-IV.

## DIHYDROBENZOFURANS

As shown in Chart V (wherein  $R$  is an alkyl group,  $R'$  is a protecting group, and  $R^1$  is as defined above), 2,3-dihydrobenzofuran analogs of type **48** can be prepared from a known compound, methyl 5-nitro-2,3-dihydro-2-benzofurancarboxylate **41** (Cham. Pharm. Bull. **1989**, *37*, 2361-2368). The nitro group of structure **41** can be converted to the Cbz-protected aniline **42** by using the method described above for the indoline analogs.

Reduction of the ester to the alcohol also as described above provides **43**. This material can be protected as an appropriate ether derivative **44**, or deoxygenated to the methyl intermediate **45** or oxidized to the aldehyde **46** via a Swern oxidation. Olefination of the aldehyde provides intermediates of type **47** which can be reduced via catalytic hydrogenation later in the synthesis. The remaining steps which lead **44**, **45**, **47** to the desired oxazolidinone analogs of type **48** are similar to these described in Charts I – IV.

## TETRAHYDROQUINOLINES

Chart VI illustrates the synthesis of requisite 6-amino-2-alkyl-tetrahydroquinolines analogs **58**. Structure **51** can be prepared through the reduction of a known compound, methyl 6-nitro-2-quinolinecarboxylate **49**, to the corresponding alcohol **50** followed by the protection of the alcohol group with an appropriate protecting group such as a silyl ether. The alcohol can also be converted to the aldehyde **52** via Swern oxidation. Olefination of the aldehyde provides alkenes of type **53**. Structure **53** can be reduced to the aminoquinolines **54** with stannous chloride. Hydrogenation of materials **54** in the presence of platinum oxide provides the requisite 6-amino-2-alkyl-tetrahydroquinolines **55** as racemic mixtures. In the case of the 2-methyl derivative, the synthesis may be shortened by starting with commercially available 6-nitro-2-methylquinoline **56**. The remaining steps that lead structure **57** to the final oxazolidinone analogs **58** are similar to the methods described in Chart I - V.

## BENZOXAZINES AND BENZOTHAZINES

Chart VII depicts the preparation of the 7-amino-3-alkyl-3,4-dihydro-2H-1,4-benzoxazines and 7-amino-3-methyl-3,4-dihydro-2H-1,4-benzothiazins. Starting from structure **59**, 7-amino-3-methyl-3,4-dihydro-2H-1,4-benzothiazins, 2,5-dinitrophenol, the formation of the triflate **60** followed by displacement with methylthiolate provides **61**. Reduction of the nitro groups with Raney nickel or stannous chloride affords the bisaniline **62** (Y = S), which can be converted to the bis-phthalimid **63** (Y = S) with BBr<sub>3</sub> in a suitable solvent such as in CH<sub>2</sub>Cl<sub>2</sub>. Removal of the methyl group according to the procedure of Young et al (Tetrahedron Lett. **1984**, 25, 1753-1756) affords the thiophenol **64** (Y = S). Alternatively, treatment of 2,5-diaminoanisole **62** (X = O) with excess phthalic anhydride affords the bis-phthalimide **63** (Y = O). Structure **63** then can be converted to the phenol **64** (Y = O) with BBr<sub>3</sub> in a suitable solvent such as CH<sub>2</sub>Cl<sub>2</sub>.

O- or S-alkylation of the phenol derivatives **64** with an appropriate  $\alpha$ -chloroketone (R = alkyl) or methyl chloropyruvate (R = CO<sub>2</sub>Me) in the presence of potassium iodide and a suitable base, such as potassium carbonate provides intermediates of type **65**. Bis-deprotection of the amino groups with hydrazine is accompanied by cyclization to the imines **66** (R = alkyl, CO<sub>2</sub>CH<sub>3</sub>). Reduction of the imines with sodium borohydride or sodium cyanoborohydride will afford the desired 7-amino-3-substituted-3,4-dihydro-2H-1,4-benzoxazines **67** (Y = O) and 7-amino-3-substituted-3,4-dihydro-2H-1,4-benzothiazins **67** (Y = S) as racemic mixtures **67** (R = alkyl or CO<sub>2</sub>Me). These compounds can be bis-protected with Cbz-chloride to give intermediates **68**. The ester side chain can be manipulated as described above to allow the preparation of other variously substituted analogs. The remaining steps that lead structure **68** to the final oxazolidinone analogs **69** are similar to the methods described in Chart I - V.

Another method for the preparation of benzothiophenes is illustrated in Chart XI. Chart XI shows the synthesis of 2-substituted-2,3-dihydro-1-benzothiophene analogs. Beginning with commercially available 2-chloro-5-nitro-benzaldehyde **104** condensation with methyl thioglycolate and subsequent decarboxylation gives **105** (J. Amer. Chem. Soc. **1948**, 70, 1955-1958). Oxidation to the sulfone **106**, followed by hydrogenation and protection of the resulting amine with the 2,5-dimethylpyrrole group (Synthesis, **1998**, 1599-1603) gives **107**. Regioselective metalation with n-butyllithium or lithium bis(trimethylsilyl)amide and alkylation with an appropriate electrophile gives **108**. Reduction of the sulfone with lithium aluminum hydride followed by removal of the protecting group and Cbz-protection gives **110**. The sulfone in **108** can be maintained in the protecting group manipulation to give the intermediate **113**. The remaining steps which lead **110** and **113** to the desired oxazolidinone analogs of type **111**, **112**, and **114** are similar to those described in Charts I-IV.

## TETRAHYDROQUINOXALINES

Chart VIII illustrates the preparation of the 2-alkyl-1,2,3,4-tetrahydro-6-quinoxalinyllamine analogs. Condensation of the commercially available 1-chloro-2,4-dinitrobenzene **75** with an appropriately protected amino alcohol derivative **72** provides intermediates of structure **76**. The aniline nitrogen of intermediates **76** can be protected with the Boc-group to give **77**. Removal of the O-protecting group followed by mesylation provides **78**. Treatment of mesylates with hydrogen in the presence of an appropriate

catalyst at high dilution results in simultaneous reduction of the nitro-groups and ring closure to yield the desired 2-alkyl-1,2,3,4-tetrahydro-6-quinoxalinyamines **79**. The remaining steps that lead structure **79** to the final oxazolidinone analogs **82** are similar to the methods described in Chart I - V.

### **2,3-dihydro-1,4-benzoxathines**

Chart IX illustrates the preparation of 3-substituted-2,3-dihydro-1,4-benzoxathiine analogs from a known compound **83**, 2-(benzyloxy)-4-nitrobenzenethiol (J. Am. Chem. Soc. **1950**, 72, 3420). Simultaneous reduction of the nitro group and removal of the benzyl moiety via catalytic hydrogenation in the presence of an appropriate catalyst and treatment with benzylchloroformate provides the protected aniline **84**. The treatment of this material with ethyl  $\alpha$ -bromoacrylate **85** according to the method described in Martin et.al. (J. Org. Chem. **1974**, 39, 1811-1814) provides the 1,4-benzoxathian intermediate **86**. The ester can be reduced to the alcohol **87**, then converted to the olefins **89** or protected as an ether **90**, or deoxygenated to give **91**. The remaining steps that lead structure **89**, **90** and **91** to the final oxazolidinone analogs **92** are similar to the methods described in Chart I - V.

If desirable, the sulfur atom can be oxidized to the sulfoxide or sulfone at various stages in the synthesis by well-known methods.

### **3,4-dihydro-2H-1,4-benzothiazines**

Chart X depicts the synthesis of 2-substituted-3,4-dihydro-2H-1,4-benzothiazine analogs. The treatment of a commercially available compound **93** with methanethiol provides compound **94**. Demethylation of the sulfur according to the method of Young (Tetrahedron Lett. **1984**, 25, 1753-1756) followed by reduction of the nitro groups with stannous chloride in refluxing ethanol provides the diaminothiophenol **95**. The treatment of **95** with ethyl  $\alpha$ -bromoacrylate **85** according to the method of described in Martin et.al. (J. Org. Chem. **1974**, 39, 1811-1814) provides 1,4-benzothiazine intermediate **96**. Biz-protection with 2 equivalents of benzyl chloroformate provides compound **97**. The ester **97** can be converted to the desired analogs **103** via methods already described above.

These compounds are useful for the treatment of microbial infections, including ophthalmologic infections, in humans and other warm blooded animals, under both parental and oral administration.

The pharmaceutical compositions of this invention may be prepared by combining the compounds of Formula I of this invention with a solid or liquid pharmaceutically acceptable carrier and, optionally, with pharmaceutically acceptable adjuvants and excipient employing standard and conventional techniques. Solid form compositions include

5 powders, tablets, dispersible granules, capsules, cachets and suppositories. A solid carrier can be at least one substance which may also function as a diluent, flavoring agent, solubilizer, lubricant, suspending agent, binder, tablet disintegrating agent, and encapsulating agent. Inert solid carriers include magnesium carbonate, magnesium stearate, talc, sugar, lactose, pectin, dextrin, starch, gelatin, cellulosic materials, low melting wax,

10 cocoa butter, and the like. Liquid form compositions include solutions, suspensions and emulsions. For example, there may be provided solutions of the compounds of this invention dissolved in water and water-propylene glycol and water-polyethylene glycol systems, optionally containing suitable conventional coloring agents, flavoring agents, stabilizers and thickening agents.

15 Preferably, the pharmaceutical composition is provided employing conventional techniques in unit dosage form containing effective or appropriate amounts of the active component, that is, the compounds of formula I according to this invention.

The quantity of active component, that is the compound of formula I according to this invention, in the pharmaceutical composition and unit dosage form thereof may be

20 varied or adjusted widely depending upon the particular application, the potency of the particular compound and the desired concentration. Generally, the quantity of active component will range between 0.5% to 90% by weight of the composition.

In therapeutic use for treating, or combating, bacterial infections in warm-blooded animals, the compounds or pharmaceutical compositions thereof will be administered

25 orally, topically, transdermally, and/or parenterally at a dosage to obtain and maintain a concentration, that is, an amount, or blood-level of active component in the animal undergoing treatment which will be antibacterially effective. Generally, such antibacterially effective amount of dosage of active component will be in the range of about 0.1 to about 100, more preferably about 3.0 to about 50 mg/kg of body weight/day. It is to be

30 understood that the dosages may vary depending upon the requirements of the patient, the severity of the bacterial infection being treated, and the particular compound being used. Also, it is to be understood that the initial dosage administered may be increased beyond the above upper level in order to rapidly achieve the desired blood-level or the initial dosage

may be smaller than the optimum and the daily dosage may be progressively increased during the course of treatment depending on the particular situation. If desired, the daily dose may also be divided into multiple doses for administration, e.g., two to four times per day.

5           The compounds of formula I according to this invention are administered parenterally, i.e., by injection, for example, by intravenous injection or by other parenteral routes of administration. Pharmaceutical compositions for parenteral administration will generally contain a pharmaceutically acceptable amount of the compound according to formula I as a soluble salt (acid addition salt or base salt) dissolved in a pharmaceutically acceptable liquid carrier such as, for example, water-for-injection and a buffer to provide a  
10           suitably buffered isotonic solution, for example, having a pH of about 3.5-6. Suitable buffering agents include, for example, trisodium orthophosphate, sodium bicarbonate, sodium citrate, N-methylglucamine, L(+)-lysine and L(+)-arginine to name but a few representative buffering agents. The compounds according to formula I generally will be dissolved in the carrier in an amount sufficient to provide a pharmaceutically acceptable  
15           injectable concentration in the range of about 1 mg/ml to about 400 mg/ml of solution. The resulting liquid pharmaceutical composition will be administered so as to obtain the above-mentioned antibacterially effective amount of dosage. The compounds of formula I according to this invention are advantageously administered orally in solid and liquid  
20           dosage forms.

5 Step 1 Preparation of 2-methyl-5-nitro-1H-indole

2-Methylindole (8.4 g, 64 mmol) in con.  $\text{H}_2\text{SO}_4$  (50 mL) is cooled to  $-5^\circ\text{C}$ . A solution of  $\text{NaNO}_3$  (5.4 g, 63.5 mmol) in  $\text{H}_2\text{SO}_4$  (80 mL) is added dropwise. After addition, the mixture is poured over ice (800 g). The resulting dark brown solid is collected and washed with cold water and dried. This solid is heated in  $\text{CH}_2\text{Cl}_2$  (220 mL) and the liquid is decanted from the remaining solid. The solvent is removed in vacuo and the residue is purified on silica gel with 15% EtOAc/hexane to give 2.5 g (22%) of the title compound. MS (EI)  $m/z$  176 ( $\text{M}^+$ ), Anal.
